

Requirements Engineering

Requirements engineering is the process of establishing

- **the services** that the customer requires from a system
- **the constraints** under which it operates and is developed

Requirements

The descriptions of the system services and constraints

that are generated during the requirements engineering process

Why do we need Requirements?

- To ensure a software solution correctly solves a particular problem, we must initially *fully understand* the problem that needs to be solved, discover *why* the problem needs to be solved and determine *who* should be involved.
- Poorly defined requirements can cause major problems to a project in both financial terms as well as added time.
- There are specific techniques we may use in the requirements engineering phase which we shall be considering during the next four lectures.

What is a Requirement?

- It may range from a **high-level abstract statement** of a service or of a system constraint to a **detailed mathematical functional specification**
- This is inevitable as requirements may serve a dual function
 - **May be the basis for a bid for a contract** - therefore must be open to interpretation
 - **May be the basis for the contract itself** - therefore must be defined in detail
 - Both of these statements may be called requirements

Types of Requirement

- **User requirements**

- Statements in natural language plus diagrams of the services the system provides and its operational constraints. Written for **customers**

- **System requirements**

- A structured document setting out detailed descriptions of the system services. Written as a contract between **client** and **contractor**

- **Software specification**

- A detailed software description which can serve as a basis for a design or implementation. Written for **developers**

Examples

- User requirement
 - We need to be able to spell check documents
- System requirement
 - The system needs to be able to spell check documents and provide autocorrect facilities. There will be support for the following languages, English, French and German will plug in support for other languages
- Software specification
 - `CheckResult spellCheck(String word, Dictionary dictionary)`
 - Word is defined in UNICODE formatted string
 - The Dictionary structure is defined in S.1.2
 - The CheckResult is defined in S.1.3 and contains a flag if the word has been found or not, plus a Vector object containing a list of possible other word suggestions depending if the word has been found or not
 - `spellCheck` will ideally use Hashing tables to improve code efficiency
 -

Requirements Readers

Functional and Non-Functional Requirements

- **Functional requirements**

- Statements of services the system should provide, how the system should react to particular inputs and how the system should behave in particular situations

- **Non-functional requirements**

- constraints on the services or functions offered by the system such as timing constraints, constraints on the development process, standards, etc. Usually defined on the system as a whole

- **Domain requirements**

- Requirements that come from the application domain of the system and that reflect characteristics of that domain

Functional Requirements

Describe functionality or system services

- Depend on the type of software, expected users and the type of system where the software is used
- **Functional user requirements** may be high-level statements of what the system should do **BUT functional system requirements** should describe the system services in detail

Examples of Functional Requirements

- All users will access the system using a user id and a password
- The system shall support the following document formats: PDF, RTF, Microsoft Word 2010 and ASCII text
- Every order shall be allocated a unique identifier (ORDER_ID)
- The system have a mechanism to help recover a user's password

Requirements Imprecision

- Problems arise when requirements are not precisely stated
- Ambiguous requirements may be interpreted in different ways by developers and users
- Consider the term '**recover password**' from previous slide..
 - **User intention** – mechanism which allows the user to view the password after going through an authentication procedure
 - **Developer interpretation** – allowing the user to reset their password so that it can be set again (e.g. using email link)
- Before development is to commence requirements should be defined as precisely as possible

Requirements Completeness and Consistency

- In principle requirements should be both complete and consistent:

Complete

- They should include descriptions of all facilities required

Consistent

- There should be no conflicts or contradictions in the descriptions of the system facilities
- In practice, it is very difficult or impossible to produce a **complete** and **consistent** requirements document

Non-Functional Requirements

- **Define system properties and constraints** e.g. **reliability**, **response time** and **storage requirements**. Constraints are I/O device capability, system representations, etc. They are often **emergent properties** of the system.
- **Process requirements** may also be specified, mandating a particular CASE system, programming language or development method
- **Non-functional requirements** may be more critical than functional requirements. If these are not met, the system is useless (e.g. key length for encrypting secure email must be ≥ 256 bits)

Non-Functional Classifications

- **Product requirements**

- Requirements which specify that the **delivered product must behave in a particular way** e.g. execution speed, reliability, security etc.

- **Organisational requirements**

- Requirements which are a **consequence of organisational policies and procedures** e.g. process standards used, implementation requirements, etc. (Java as programming language)

- **External requirements**

- Requirements which arise from factors which are **external to the system and its development process** e.g. interoperability requirements, legislative requirements, etc. (Must conform to FIPS

Non-Functional Requirement Types

Non-Functional Requirements Examples

- **Product requirement**
 - All encryption should use the Advanced Encryption Standard
- **Organisational requirement**
 - The system development process and deliverable documents shall conform to the process and deliverables defined in coding and documentation standard XYZCo-SP-STAN-95
- **External requirement**
 - The system shall not disclose any personal information about customers apart from their name and reference number to the operators of the system
- **Performance requirement**
 - The system should respond to a user's request for information in less than 0.1 seconds during "peak-time" and 0.01 seconds during "normal time".

Goals and Requirements

- **Non-functional requirements** may be very difficult to state precisely and imprecise requirements may be difficult to verify.
- **Verifiable non-functional requirement**
 - A statement using some measure that can be objectively tested
- **Goal**
 - A general intention of the user such as ease of use
- Goals are helpful to developers as they convey the *intentions* of the system users

Examples

- **An example system goal**
 - The system should be easy to use by experienced controllers and should be organised in such a way that user errors are minimised.
- **An example verifiable non-functional requirement**
 - Experienced controllers shall be able to use all the system functions after a total of two hours training. After this training, the average number of errors made by experienced users shall not exceed two per day.
